

Serum Monoclonal Gammopathy Screen

Notes:

1. If SFLC assay is abnormal and SIFX is negative, it may be necessary to obtain a 24-hour urine for both protein electrophoresis and immunofixation to rule out light chain disease or amyloidosis.
2. If SIFX reveals a monoclonal gammopathy, it may be useful for staging and prognosis to obtain a 24-hour urine for both protein electrophoresis and immunofixation.
